1. Introduction

Network management supports the end user of an EIB network during the installation, configuration and maintenance of the EIB network. The tasks of EIB network management are configuration management, security management, fault management and performance management.

The whole network management is based on connection-oriented services of the application layer (see Chapter 3/3/7 “Application Layer”), and on the object server functionality described in Chapter 3/4/1 “User Layer”.

This Chapter is currently being reworked. A new description is foreseen for a following update of these EIBA Handbook Series.

To be completed.
